5 Abstract

Traditionally, women did most of the housework labor while men were involved in paid labor. This role-understanding is subject to change, so today a more equal housework distribution is commonly associated with higher satisfaction. Nevertheless, past research has shown that this association might only be partly true as gender role beliefs, tied to religion or not, could significantly influence the satisfaction based on housework 10 distribution between male and female partners. In our research, we aim to further analyze 11 the relationships between housework distribution and satisfaction using a dyadic approach. 12 Participants were 166 heterosexual married couples living in the US. We found that gender role beliefs but not religion moderated the relationship between females' perceived amount of housework and their satisfaction. While satisfaction declined for liberal female partners who did more housework, it remained on a constant level for females with traditional gender role beliefs, regardless of the amount of housework they did. Our results support 17 past research and suggest that females who are doing the major amount of housework to 18 this day, are still seen as the main actors when it comes to housework responsibilities. 19 Female partners, therefore, differed a lot more in how satisfied they were compared to their male partners. Our findings are relevant in the context of couples therapy and are likely to 21 be related to health-related outcomes connected to satisfaction and overall health issues. 22

23 Keywords: housework distribution, satisfaction, gender role beliefs, religion, APIM

Satisfying housework division? Gender role beliefs and religion as moderators of housework division and satisfaction

# Housework distribution and satisfaction: The moderating role of gender role beliefs and religion

# 28 Introduction

Gender role beliefs have been widely debated in society for decades, as this
controversial concept subjects men and women to gender-specific roles. One audible voice
in this discourse is the voice of the Church. Pope Francis, for example, recently described
gender theory as evil and dangerous because "[i]t would make everything homogeneous,
neutral. It is an attack on difference, on the creativity of God and on men and women"
(League, 2020).

Traditionally, the majority of housework has been done by women while their male 35 partners have been involved with paid labor. This distinction of gendered labor has been 36 subject to change over the past few decades. Although most women in heterosexual couples 37 are now as equally involved in paid labor as their male counterparts are, they often still do the majority of the housework (R. Forste & Fox, 2008; Leopold, 2019; Mikula, Freudenthaler, Brennacher-Kroll, & Brunschko, 1997). These evolving trends illustrate how traditional and conservative gender role beliefs are slowly becoming more liberal and less stringent in everyday life. Gender role beliefs still heavily influence women's role in society, from their job prospects to gender-based income inequalities. Even though men are now doing more housework than before the "gender revolution" (Goldscheider & Rico-Gonzalez 3, 2014), the unequal distribution of housework has been found to result in lower satisfaction levels in female partners (Leopold, 2019). However, since past research (Baxter & Western, 1998; Forste & Fox, 2012) has shown that this relationship between

housework distribution and satisfaction is complex, we will assess the extent to which two

variables, religion and gender role beliefs, strengthen or dampen this relationship. This will
be done using a dyadic approach. The dyadic approach has the advantage of including
interactions between partners and therefore gets to the core of the relationships of interest
which has not been the standard approach in prior research. This approach will strengthen
this study by specifying the effects of each partner's gender role beliefs and religion on the
relationship between housework distribution and satisfaction. This research topic is
important to investigate as it can help prevent future relationship conflicts and
housework-related stress, which could impact negative health outcomes such as depressive
symptoms, as well as divorce rates Glass & Fujimoto (1994).

Numerous past studies have analyzed the growing relationship between housework 58 distribution and satisfaction. Nelson (1977) found that almost half of the housewives in the 59 sample were intrinsically satisfied, but did not explain why the satisfaction differed. These 60 findings are specifically related to housework tasks that are perceived as "female-typed", 61 which include everyday chores such as laundry and cleaning. In most articles, the "female-typed" housework tasks were seen as prototypical housework tasks that significantly affected satisfaction levels (Benin & Agostinelli, 1988; Ellison & Bartkowski, 2002). Using data from the late 1900s, Baxter and Western (1998) found that regardless of an extremely uneven distribution of housework labor, only 13-14\% of women were dissatisfied. In contrast, Mikula et al. (1997) concluded that women who did more housework than men were significantly less satisfied. Their partners who performed less housework showed higher satisfaction levels. These rather contradictory findings could be explained by the aforementioned societal changes concerning gender role beliefs and the "gender revolution" that can change one's judgment and satisfaction with housework 71 distribution (Goldscheider & Rico-Gonzalez3, 2014; Okulicz-Kozaryn & Rocha Valente, 2018). This is in line with more recent studies that found that women were more unsatisfied with the housework distribution than men and that equal housework distribution was related to subjective marital equity (Charbonneau, Lachance-Grzela1, &

Bouchard 1, 2019; Spitze & Loscocco, 2000). Therefore, it is not appropriate to assume that an equal distribution of housework labor is the only predictor of satisfaction. It therefore 77 seems important to consider the personal perception concerning housework. Greater 78 underbenefit, the act of one partner doing more housework than the other resulting in 79 negative emotions, has been shown to relate to lower marital quality (DeMaris, 2010). This notion of underbenefit contradicts past research in which female partners evaluated their 81 uneven housework distribution in a positive way, which points us towards the importance of subjectivity and the personal standard with which each situation is assessed. One way in which individuals differed that addresses these subjective standards is gender role beliefs. Buunk, Kluwer, Schuurman, and Siero (2000) showed that egalitarian women tended to be more dissatisfied with an unequal distribution of housework in comparison to traditional women. Likewise, Evertsson (2014) reported that people who held egalitarian gender role beliefs were more satisfied with a more equal distribution of housework. For egalitarian couples, it was observed that housework was more equally distributed, while in households that held traditional views women still did the majority of the housework (Greenstein, 1996). This shows that couples strived towards a distribution of housework that satisfied them (Benin & Agostinelli, 1988), but this balance looked different for everyone. Researchers found the highest satisfaction levels in traditional couples when both partners had varying involvements in household tasks and the subjective incongruence between attitudes and behaviors regarding family roles was low (Forste & Fox, 2012). This means that partners were satisfied when they valued equality on a cognitive level and had an actual equal distribution of housework at home. It is therefore necessary to assess the effect 97 of gender role beliefs on the relationship between housework distribution and satisfaction, as prior research suggested that this relationship could be reversed when comparing 99 traditional and egalitarian couples. 100

While most studies focused on female contributions to housework and its impact on satisfaction, some studies also looked at male partners. It was found that men who were

married to women with traditional views performed less housework than men who were 103 married to women with egalitarian views (Greenstein, 1996). These men who did less 104 housework were found to have greater satisfaction. This illustrates how gender role beliefs 105 moderate the relationship between housework distribution and satisfaction since the men 106 who were married to women with higher gender role beliefs (traditional women) performed 107 less housework and were, therefore, more satisfied. This unequal housework distribution 108 can have severe health consequences, as a greater housework distribution has been 109 associated with higher levels of depression (Glass & Fujimoto, 1994). Since prior research 110 only focused on either the male or female partner, it did not provide a dyadic analysis of 111 couples. This led to incomplete results which did not reveal all the information needed to 112 fully understand the underlying dynamics between these variables. Therefore, we will use a 113 dyadic approach to assess this relationship.

Another way through which individuals might differ that also moderates the 115 relationship between housework distribution and satisfaction is religion. Religion has been 116 an important factor in relationship dynamics for decades. It provides a powerful framework 117 for gender norms and beliefs that are sanctified and therefore qualitatively different from 118 non-religious norms (M. Hunt & Jung, 2009). For most religious denominations, religiosity 110 is connected to patriarchal gender role attitudes at home (Goldscheider & Rico-Gonzalez3, 120 2014). As shown in the quote by Pope Francis, religion and religious institutions are still 121 powerful societal actors that influence intrinsic values and beliefs to this day (Musek, 122 2017). Religion and varying gender beliefs continue to heavily impact the expectations of 123 female and male responsibilities and the distribution of housework roles between heterosexual, religious couples. Research has shown that conservative gender role models 125 were more commonly implemented if one partner strongly believed in religious gender 126 stereotypes (Blair & Lichter, 1999). Females' beliefs greatly influenced the distribution of 127 household labor and housework patterns (Ellison & Bartkowski, 2002). While conservative 128 evangelical women invested more time in housework in general and specifically in

female-typed housework, the husband's religious affiliation did not affect the amount of housework as much. Ellison and Bartkowski (2002) explained this by hegemonic 131 masculinity superseding subcultural gender norms. However, while many religious couples 132 have started to defy this dynamic, some still continue to follow this structure. Not only 133 does religion affect the distribution of housework, but prior research has also suggested 134 that in religious couples, a small contribution towards housework from men was found to 135 lead to higher female partner satisfaction (DeMaris, Mahoney, & Pargament, 2013). 136 Although previous studies have suggested that religion is related to housework distribution, 137 the moderating impact of religion on the relationship between housework distribution and 138 satisfaction has not been sufficiently investigated from both partners' perspectives. Once 139 again, most studies have lacked a dyadic approach as they either focused on either the male 140 partner or the female partner, which increases the need to perform a dyadic analysis. It is especially interesting to analyze these relationships further in a dyadic way as men's and women's relationship patterns between housework distribution, satisfaction, and religion 143 could look very different. Because the religious landscape as well as overall societal structures, including hegemonic masculinity, are currently subject to societal change, it will 145 be interesting to see whether patterns might have changed during the last years and therefore differ from previous findings.

In our study, we examined the relationship between housework distribution and 148 satisfaction in a way past research has not done yet. This included a dyadic investigation 149 of the impact of the moderating factors of gender role beliefs and religion on housework 150 distribution and satisfaction of both partners. We more specifically aim to find out whether the relationship between housework distribution and satisfaction is moderated by 152 gender role beliefs and religion, and whether gender-related characteristics affect one's own 153 (actor effects) and the partner's outcomes (partner effects). We hypothesize that the higher 154 the amount of housework of an egalitarian partner, the lower the satisfaction is for an 155 unequal housework distribution (Hypothesis 1a). For women with traditional gender role 156

beliefs, a higher amount of housework is associated with a higher level of satisfaction than liberal women (Hypothesis 1b). Male partners with traditional gender role beliefs are 158 expected to be more satisfied if their wives did more housework (Hypothesis 1c). Because 159 prior research lacks dyadic analyses, specifying the effects of each partner's gender role 160 beliefs on the relationship of interest will strengthen the current study. Similar to the 161 moderating role of gender role beliefs, it is expected that because religion is connected to 162 more traditional relationship ideals, it can be another moderator for the relationship 163 between housework distribution and satisfaction. It is hypothesized that in non-religious 164 couples, more housework is related to lower satisfaction with housework distribution 165 (Hypothesis 2a). For religious women, it is expected that more housework is connected to 166 greater satisfaction (Hypothesis 2b) and religious male partners are expected to be more 167 satisfied if their wife does more housework (Hypothesis 2c).

Besides the hypothesized relationships described above, we will include exploratory 169 analysis of gatekeeping behaviors within the couples. Gatekeeping is defined as behaviors 170 that prevent equal work performed by both partners in a relationship (Allen & Hawkins, 171 1999). According to Allen and Hawkins (1999), a mother's reluctance to share familial 172 responsibility inhibits greater father involvement in family work, resulting in an unequal 173 housework distribution. We will investigate whether gatekeeping in females is related to 174 gender role beliefs and therefore mediates the relationship between gender role beliefs and 175 satisfaction. Gatekeeping behaviors by one partner can shut out the other partner from performing a household task.

178 Method

### 179 Participants

Originally, 364 individuals in a partnership living in the United States of America participated in the study. In our analysis, we excluded all non-heterosexual couples and

participants that did not have any partner variables available. In the end, N = 166 couples (N = 332 individuals) have been included in the analysis. Women and men from the final sample of 166 adult couples were 44.83 (SD = 7.73, range = 26-74) and 46.85 (SD = 8.90, range = 30-65) years old, respectively.

The relationships, at the time of the study, have been between 1.33 and 41.25 years long, with an average of 18.47 years (SD = 9.51). The average yearly income was 66362 USD (SD = 76599 USD) for men and 76363 USD (SD = 57133 USD) for women. 29.5 % of the women and 12.7 % of the men worked from home, 59.6 % of the women and 64.5 % of the men did not work from home. No answer to this question was given by the remaining participants (22.9 % of the men and 10.8 % of the women).

We further looked at men and women based on their religion and race.70 is the % of
the sample that identified as Christian, 4 % as Athiest, 4 % as Agnostic, 5 % as Jewish, 5
% as Hindu and 2 % as Muslim. 5 % identified had a religious orientation apart from the
mentioned ones and 4 % preferred not to answer this question. 74 % of the sample were
White, 1 % Hispanic and White, 7 % Black, 11 % were Asian, 6 % were Hispanic and 1 %
were Middle Eastern.0 % of the participants were another race and 1 % of the participants
preferred not to answer the question.

#### 199 Procedure and Measures

Participating couples in this study were recruited online. The study was conducted in 2012 2020 by Randi Garcia and contained two parts: The first part included a battery of questionnaires that included all variables used in this study. In a second part, both partners were asked to fill out a daily survey for two weeks. Participants were instructed to not share their responses with their partners. Participants were compensated for the study if both, they and their partner, completed the questionnaires. For the second part, the daily measures, each participant received \$2 per day. All participants gave their informed

consent to participate in this study. In this analysis, selected data from the first batterie of questionnaires were used. The measures of interest are introduced below. To assess gender differences in relevant outcome variables, t-tests were used. The multivariate analysis of variances (MANOVA) was conducted to assess the relationship between our main variables, housework distribution and satisfaction and their moderators gender role beliefs and religion. The analysis was conducted in R (R Core Team, 2020) and written with the R papaja package (Aust & Barth, 2020).

Demographic Variables. Participants were asked to report several demographics.

We were interested in the participants' gender, the couples' relationship length, each

partner's yearly income, their work from home status, religious affiliation, and race.

**Housework Distribution.** The scale Who does what?, developed by Cowan and 217 Cowan (1992), measures the percentages of who performs which chores and household 218 activities through 14 statements that participants had to rate on a five-point Likert Scale 219 according to how often they do the chore mentioned in the statement (1 =  $\theta$  - 20 % to 5 = 220 80 - 100 %). Example questions include "make beds or change bed linens", and "take out 221 garbage, recycling". Based on prior research that differentiated between female and 222 male-typed tasks, and results from our own correlation analyses that showed high 223 correlations between typically female-typed tasks that were not or negatively related to 224 typically male-typed tasks, we decided to split this scale into traditionally male and traditionally female-typed tasks and only use a mean score of contributions to female-typed tasks for our analysis. The scales were reliable with a Cronbachs Alpha of 0.90 for female tasks and 0.83 for male tasks. The ICC was -0.84 for female tasks and -0.71 for male tasks. 228

Gender Role Beliefs. Gender Role Beliefs are quantified through the Gender Role
Belief Scale (GRBS) developed by Kerr and Holden (1996). This self-report scale measures
gender ideology and beliefs about appropriate behavior for men and women. Example
ideologies include "women should not expect men to offer them seats on buses" (reversed)
and "the husband should be regarded as the legal representative of the family in all

Table 1

Gender Differences in Outcome Variables

	Means (Female)	SD (Female)	Means (Male)	SD (Male)	t Statistic	p Value
Housework Distribution (Female Tasks)	75.46	13.49	50.73	16.46	11.49	<.001
Gender Role Beliefs	2.64	0.70	2.89	0.67	-5.63	<.001
Housework Satisfaction	3.79	1.16	3.95	0.94	-1.63	0.11

Note. This table was created with apa\_table(). The Housework Distribution indicates percentages. Gender Role Beliefs and Housework Satisfaction have been reported on a 1-5 Likert Scale.

matters of law". Participants rated how much they agreed with these sentences on a five-point Likert Scale ( $1 = Strongly \ Disagree$  to  $5 = Strongly \ Agree$ ). The scale showed high reliability with a Cronbach's Alpha of 0.89and an ICC of 0.64.

Housework Satisfaction. To quantify the satisfaction with the division of housework tasks between the two partners, we asked them "how satisfied are you with the division of household tasks?". Participants responded on a 5 point Likert scale (1 = "very dissatisfied" to 5 = "very satisfied"). The ICC was 0.27.

Results Results

### 242 Preliminary Analysis

Results of the preliminary analysis are shown in Table 1. T-tests showed that men are doing significantly more male housework tasks than women while women perform significantly more typically female tasks around the house. Satisfaction with the distribution of housework did not differ significantly between male and female partners.

# 47 Analysis Strategy

To test our hypotheses that gender role beliefs and religion moderate the relationship 248 between housework distribution and satisfaction, we used multilevel modeling and the 249 Actor-Partner Interdependence Model (Kenny, Kashy, & Cook, 2020)). The APIM 250 measures the effect of the explanatory variables for both members in a dyad at the same 251 time, so actor as well as partner effects could be considered in our analysis. This way, it is 252 possible to see how one partner's housework distribution affects both their own satisfaction 253 with the housework distribution (actor effect) and their partner's satisfaction with the 254 housework distribution (partner effect). This analysis looked at the moderating effect of 255 each partner's gender role beliefs on the two actor effects (shown in Figure 1) as well as on 256 the partner effects. Our research studied people in relationships, where each pair in a 257 relationship is referred to as a dyad. Since we were working with dyadic data, our data was 258 not independent. For example, the amount of housework one partner does will be 259 correlated with how much housework the other partner does. This will result in correlated 260 residuals. To account for the nonindependence, the APIM estimated the correlation between residuals for satisfaction between dyad members after accounting for housework 262 distribution and gender role beliefs.

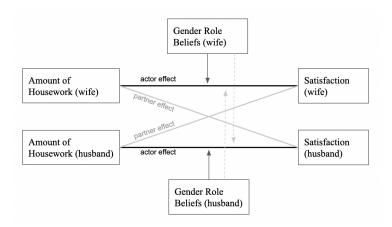

Figure 1. Schematic representation of actor and partner effects in the APIM moderated by gender role beliefs.

#### Main Results

289

Gender Role Beliefs. All relevant results of the moderation analysis in the 265 APIM are shown in Figure 2. It was shown that for husbands and wives, a higher amount 266 of housework was significantly related to a lower satisfaction (wives b = -0.02, p = 0.02, SE267 =0.01; husbands b = -0.03, p = 0.01, SE = 0.01). For the female partners, their own gender 268 role beliefs significantly moderated the relationship between their housework distribution 269 and their satisfaction with the housework distribution, b = 0.07, p = <0.01, SE = 0.02). 270 When the wives had higher gender role beliefs, which means more conservative, their 271 satisfaction with the housework distribution tended to be higher, while keeping their own 272 housework distribution constant at the mean. Wives who have low gender role beliefs, which means they are more liberal, reported lower satisfaction with an increasing amount of housework they had to do. Women with more conservative gender role beliefs (high 275 value) did not show a significant decrease in satisfaction with an increasing amount of 276 housework (see Figure 3). The husband's gender role beliefs significantly moderated the 277 relationship between the wife's amount of housework and the wife's satisfaction with the 278 housework distribution (b = -0.06, p = 0.01, SE = 0.02). When the husbands had more 279 conservative gender role beliefs, the wife's satisfaction decreased by -0.06 while keeping the 280 wives housework distribution constant at the mean. As the amount of housework increases 281 for wives whose husbands have low gender role beliefs, their satisfaction remains constant. 282 When housework increases for wives whose husbands have high gender role beliefs, their 283 satisfaction decreases (see Figure 4). Moreover, a marginally significant moderation effect 284 was found for the relationship between the husbands amount of housework and the wife's 285 satisfaction which was moderated by the wife's gender role beliefs (b = 0.03, p = 0.10, SE 286 = 0.02). When wives had more conservative gender role beliefs, their satisfaction tended to 287 be higher, while their husbands housework distribution was held constant at the mean.

Since we used distinguishable dyads, gender was a built-in moderator. To see if the

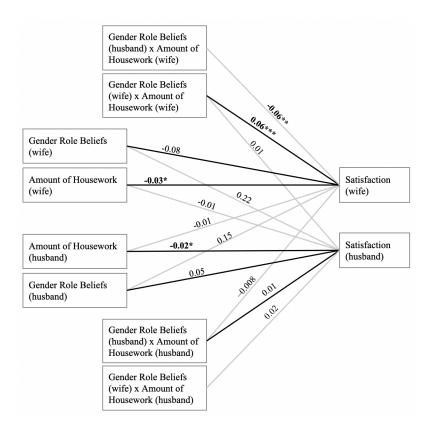

Figure 2. Moderation effects in the APIM. Values shown in the figure are  $\beta$  coefficients. \* p < .05, \*\* p < .01, \*\*\* p < .001.

moderation effects differed significantly by gender, we looked at the three-way interactions between gender, housework distribution, and gender role beliefs. We found two significant 291 gender differences in the moderation effects. The interaction between the actor's housework 292 and their own gender role beliefs was significantly different for husbands and wives (b 293 =0.06, p=0.03, SE=0.03). The moderation effect of one's own gender role beliefs was 294 0.06 units higher for women than men, meaning the moderation effect of gender role beliefs had a significantly larger positive effect on satisfaction for wives than for husbands. In addition, the interaction between the actor's amount of housework and their partners gender role beliefs was significantly different for husbands and wives (b = -0.08, p = 0.01, SE = 0.03). The moderation effect of the partner's gender role beliefs was -0.08 units lower 299 for women than men which means that the moderation effect of the husband's gender role

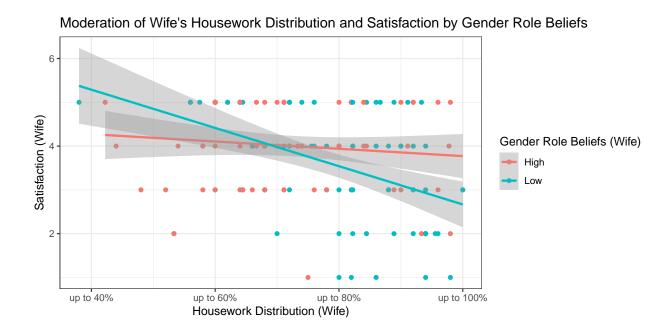

Figure 3. Moderation of wife's housework distribution and satisfaction by gender role beliefs. Housework distribution in %, Satisfaction and gender role beliefs were measured with a 5 point Likert scale (1 = liberal, 5 = conservative).

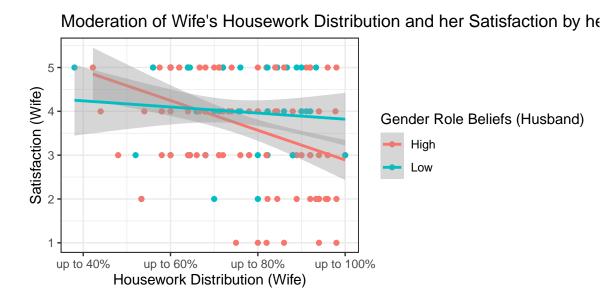

Figure 4. Moderation of wife's housework distribution and her satisfaction by their husbands gender role beliefs. Housework distribution in %, Satisfaction and gender role beliefs were measured with a 5 point Likert scale (1 = liberal, 5 = conservative).

beliefs had a significantly larger negative effect on her actor effect of housework on satisfaction compared to how the wife's gender role beliefs affected the relationship between housework distribution and satisfaction for her husband.

Religion. No significant relationships between any of the variables have been found in the APIM model including the moderator religion ( $p_{\rm all} > 0.19$ ). Religion did therefore not moderate the relationship between housework distribution and satisfaction for wives and husbands.

# 308 Exploratory Results

In order to be able to find possible explanations for the association between gender 309 role beliefs and satisfaction that we found in our analysis, we conducted a simple mediation 310 analysis, investigating whether the wife's gatekeeping mediated the relationship between 311 her gender role beliefs and her satisfaction and therefore could explain the patterns found 312 in the prior analysis. Are women with higher gender role beliefs more likely to gatekeep 313 housework tasks which would in turn lead to a higher satisfaction? Linear models were 314 calculated for all paths to see whether all paths are significant first before we calculated the 315 mediation effect in a second step. 316

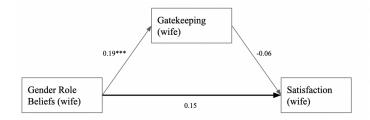

Figure 5. Proposed mediation model with wife's gatekeeping as the mediator of the wife's gender role beliefs and satisfaction. Values shown in the figure are  $\beta$  coefficients. \* p < .05, \*\* p < .01, \*\*\* p < .001.

As seen in Figure 5, no significant relationship between gender role beliefs and satisfaction was found, despite the moderating effect of gender role beliefs that was found previously. Because only the relationship between gender role beliefs and gatekeeping has been significant, a full mediation analysis was no longer appropriate to conduct. Instead, we conducted post-hoc t-tests to get a better sense of the relationship between gender role beliefs and gatekeeping. We found that liberal women gatekeep significantly less than traditional women (t(n) = -24.68, p = <0.01).

325 Discussion

# 326 Summary

The goal of the current paper was to further investigate the relationship between 327 housework distribution and satisfaction amongst heterosexual couples, based on their 328 individual gender role beliefs and religion. Gender role beliefs were found to be a 320 significant moderator for the relationship between housework distribution and satisfaction 330 in female but not male partners (Hypothesis 1a, b, c), while religion did not moderate the 331 relationship (Hypotheses 2a, b, c). The data showed that liberal women were more 332 dissatisfied with an uneven housework distribution (Hypothesis 1a), as opposed to 333 conservative women who did not show the same decline in satisfaction with a higher 334 amount of housework (Hypothesis 1b). We did not find that male partners with traditional 335 gender role beliefs were more satisfied if their wives did more housework (Hypothesis 1c). Hypothesis 1a has therefore been disproven for male but not female partners. Hypothesis 2b stating that a higher amount of housework is associated with a higher level of 338 satisfaction in conservative compared to liberal women, was not falsified by our research. 339 Hypothesis 1c and hypotheses 2a, b, and c that refer to the different moderating effects of 340 religion had to be rejected. 341

#### 2 General discussion

Gender role beliefs. Most of our results looking at gender role beliefs as a 343 moderator are in line with existing research that found a moderating effect of gender role beliefs on the relationship between housework distribution and satisfaction (Buunk et al., 2000; Evertson, 2014). Egalitarian women tended to be more dissatisfied with an unequal distribution of housework in comparison to traditional women, and participants who held egalitarian gender role beliefs were more satisfied with a more equal distribution of housework (Buunk et al., 2000; Evertson, 2014). Overall, our results support past research suggesting that unequal housework distribution can be related to low satisfaction, 350 especially for women with liberal gender role beliefs (Forste & Fox, 2008; Leopold, 2019). 351 Our results also connect to Leopold's (2019) findings showing an overall decline in female 352 happiness even though women do less housework than in times before the "gender 353 revolution", while men's satisfaction increased when they did more housework. It is 354 possible that especially with steps in the direction of equality, the perceived inequality in 355 housework distribution becomes much more visible which makes liberal women less 356 satisfied. Men, on the other hand, might feel good about their steps towards a more equal 357 housework distribution that fits their beliefs, even if housework is still not equally 358 distributed. Our results also support past research suggesting that women, on average, did 359 more housework than men and were significantly less satisfied (Mikula et al., 1997; 360 Charbonneau et al., 2019; Spitze & Loscocco, 2000). Nevertheless, Mikula and colleagues 361 did not distinguish between liberal and traditional women which we found to have an 362 important influence on the satisfaction level and therefore missed relevant information. We further dissected these patterns with our findings that traditional women tended to be more satisfied with an increasing amount of housework than liberal women. 365 Our findings further clarify conflicting results in past research by adding a relevant 366 layer, gender role beliefs, as a moderator of this relationship. Gender role beliefs could 367 explain the contradicting results described in the theory of underbenefit (Okulicz-Kozaryn

& da Rocha Valente, 2018) and Baxter and Western's (1998) findings that the majority of 369 women were satisfied with an unequal housework distribution. We suggest that the theory 370 of underbenefit can be directly related to liberal women in our own sample, criticizing that 371 there is no equal housework distribution while Baxter and Western's (1998) findings might 372 only apply to women with traditional gender role beliefs. As egalitarian partners should 373 both value an equal housework distribution, it is interesting that our results only showed a 374 decline in satisfaction with an increasing amount of housework for egalitarian women but 375 not for men. This may be due to the fact that most men thought on average that they did 376 an equal amount of housework. Women, in contrast, had a higher variability in their 377 housework contribution as well as a higher average of their perceived housework, which 378 makes it more likely to find differences within the group of women. Furthermore, women 379 may still be held accountable for domestic work, especially when it comes to traditionally female-typed tasks. This may result in a stronger emotional reaction and a bigger effect on 381 satisfaction than in men. In the gender revolution movement, mostly women were fighting against prescribed role attributions which is why it seems reasonable to assume that for our 383 results, differences between men and women concerning the moderating effect of gender 384 role beliefs could at least be partly explained by how active each partner's role is in 385 "female-typed" housework (Goldscheider & Rico-Gonzalez3, 2014). As suggested by Ellison 386 and Bartkowski (2002), hegemonic masculinity might still supersede subcultural gender 387 norms which results in a societal structure where men are not held socially accountable for 388 domestic work. This societal structure points towards the fact that a female's active part 389 in housework is not always chosen by them but assumed by society. 390

Gatekeeping. To further investigate the presumption that the acceptance of the
prescribed active female role in housework could be related to our findings, we conducted
an exploratory analysis using the concept of gatekeeping. Although we did not find a
mediation effect as we expected, we did find that gender role beliefs and gatekeeping were
associated with each other for females. Conservative women were more likely to gatekeep

than liberal women. This speaks for the fact that conservative women actively chose to engage in more housework. Gatekeeping can therefore be a useful construct to consider when looking at how gender role beliefs moderate the relationship between housework distribution and satisfaction.

Religion has not been shown to interact with the relationship between Religion. 400 housework distribution and satisfaction. Despite prior research finding similar significant relationships for religion as with gender role beliefs, our results suggest otherwise. This is 402 especially interesting because religion could be directly associated with more traditional 403 gender role beliefs. However, research suggests that religiosity as a dichotomous construct 404 may be too broad to find any differences. The variability of gender norms within the group 405 of people who identify as religious may be too big, which is why it would have been 406 important to look at religious subgroups that can be defined based on the relevance and 407 conservatism of the specific religious denomination for the individual. Our results therefore 408 also show that it is inappropriate to assume things about a person's gender role beliefs just 409 based on religion. It has been shown that although there might be an overlap of ideals 410 between religions, they should not be all lumped together (Civettini & Glass, 2008; 411 DeMaris, 2010). A strong connection between religion and gender role beliefs can be 412 expected for a rigid and conservative orientation. Religious norms and values, in a 413 conservative setting, often include sanctified beliefs, which means they are perceived as 414 coming from a higher, divine power, like a god. Sanctified, "vertical/divine" beliefs can be 415 particularly rigid and hard to falsify. Since conservative religious women tend to have 416 sanctified beliefs about gender roles and liberal religious women don't, it is likely to find differences in the gender role beliefs between liberal and conservative religious individuals 418 (Bloom, 2012; Dollahite, Marks, Babcock, Barrow, & Rose, 2019; M. E. Hunt & Jung, 2009). Especially because a moderating effect of gender role beliefs has been found in our 420 research, it is likely that with a more detailed assessment of religion, we could have found 421 significant results as well. 422

**Limitations and future research.** As discussed before, the biggest limitation in 423 this research might have been that religion has been assessed as a dichotomous variable 424 which limits the comparability to prior research and might have prevented us from finding 425 any moderating effects of religion on the relationship between housework distribution and 426 satisfaction. Future research should include a more detailed assessment of religiosity, 427 religious subgroups, and the relevance of religion. Moreover, potential confounding 428 variables that could significantly influence both housework distribution and satisfaction 420 levels are overall psychological well-being (Bird, 2000), overall economic resources 430 (Erickson, 2005), negotiation processes that distinguish couples and influence how they 431 deal with conflicts that may evolve because of unequal housework distribution between 432 partners (Charbonneau et al., 2019), and marital generosity which could be related to 433 religion and leads to higher satisfaction in women that do more housework but value when their husbands even do a little bit of housework, too (Wilcox & Dew, 2016). Future 435 research could include these variables and control for potential differences in the satisfaction that might be explained by the aforementioned constructs. Our dataset only 437 included heterosexual couples which is a constriction that can be overcome in future 438 research. It would be valuable to investigate whether actor and partner effects vary between different partnership models and whether same-sex couples choose a more equal 440 approach to housework distribution. If less decline in satisfaction is observable with a 441 higher amount of housework in same-sex couples, this could be because traditional gender 442 roles might play a lower role in same-sex couples than in heterosexual couples (Giddings, 443 1998). It is also important to note that the data have been collected during the Covid-19 444 pandemic where a lot of the participants were working from home, which might have 445 changed overall patterns in housework distribution. It would be valuable to compare our 446 data to a sample that has not been affected by the pandemic.

Summary and implications for practice. Gender role beliefs but not religion
have been shown to have a moderating effect on the relationship between the amount of

housework and satisfaction of female partners in heterosexual relationships. While for liberal women, satisfaction declined with a higher amount of housework they perceived to do, no such relationship was found for women who held more conservative gender role beliefs.

Analyzing the underlying reasons, such as a mismatch between gender role beliefs 454 and the actual distribution of housework, for poor satisfaction levels in couples could be 455 used to help prevent health-related issues such as depression and outcomes like divorce 456 (Glass and Fujimoto, 1994; Ruppanner, 2012). Findings could be used for couples therapy 457 and suggest that working on gender role beliefs instead of just looking at the housework 458 distribution as the source of arguments and fights would be valuable to increase 459 satisfaction levels in relationships. Our findings are a reminder of how diverse people's 460 beliefs are and show that satisfaction can be reached in different ways. It is important to acknowledge that people have different belief systems and moral norms that can contribute to their satisfaction. Our results can furthermore give an impulse to fight for a change of societal norms and to facilitate more equal housework distribution through equal pay for 464 women and normalizing housework for men as an unequal housework distribution was 465 associated with the lowest satisfaction levels in women. There are still many aspects to be 466 considered in future research to get to the core of relationships between housework 467 distribution and satisfaction but our research contributes to a growing body of research 468 that tries to understand relationships between gender role beliefs, housework distribution, 469 and satisfaction in a dyadic setting and can give impulses for future research. 470
